A programmable logic controller (PLC) is a type of programmable controller that is used to perform a variety of control functions in an automated industrial or commercial process, although it may be used in other settings. A PLC is usually programmed to respond to and control the process according to a set of input signals and output control instructions, and may be programmed to regulate the process in response to sensed parameters. A PLC may be programmed in hardware, firmware, or software. The control instructions may be stored in a nonvolatile memory component or components within the PLC. A PLC may be configured as a controller, in which case it may send output control instructions to devices such as actuators and motors. The PLC may be configured as an embedded controller, in which case it may monitor and/or sense variables, such as temperature, pressure, and/or other relevant data, to control the devices. The PLC may be used to control an electric motor, a machine, an assembly line, and the like. Some process control systems use a “smart” PLC, which includes both a traditional PLC (e.g., a ladder logic or flow chart PLC) and an input/output (I/O) control module. The I/O control module is used to generate control instructions for output devices (e.g., motors, pumps, fans, valves, and the like). Thus, by providing such an I/O control module, the smart PLC may be programmed as a controller that responds to input signals and outputs control instructions to the output devices. As compared to the traditional PLC, the I/O control module may have more control input/output (I/O) channels, and is typically more modular and extensible. However, the traditional PLC is typically still a primary programmable control for the process. The I/O control module is typically a secondary programmable control for the process. The I/O control module may be programmed in different ways than the traditional PLC. United States Court of Appeals 2d92ce491b
